

TECHNICAL PROPOSAL · PART 1 OF THE PLATFORM ROADMAP

The app is ready. Now it needs a **backend**.

Strolla Health today is a beautifully finished Flutter app with live BLE step tracking, GPS workouts, community, challenges and sharing — but almost everything social and historical runs on **placeholder data that lives only on one phone**. This document shows exactly what a Python backend unlocks, and how we deliver it in safe, demo-able phases.

13

screens already built &
polished in the app

7+

headline features currently
running on mock data

1

phone — the only place a
user's data exists today

0

user accounts. No login,
no recovery, no sync

WHERE WE ARE TODAY

Everything lives — and dies — on one phone

The hardware pipeline is real and works well. But there is no server: nothing is backed up, nothing is shared between users, and every social feature is a façade rendered from hard-coded data inside the app.

⚠ User deletes the app → every step, workout and streak is gone forever

THE GAP

What the UI promises vs. what actually works

Audit of the shipped screens. The UI sets user expectations that the current app cannot honour.

FEATURE IN THE APP	TODAY	WHY
BLE step counting	REAL	Live nRF7002 stream + mock fallback
GPS workout sessions	REAL	On-device GPS + local SQLite
Daily goal & streaks	PARTIAL	Streak computed from fake week data
Weekly / monthly stats	MOCK	30-day charts are hard-coded arrays
Community feed & posts	MOCK	No server — posts go nowhere
Friends & connections	MOCK	"842 connections" is a hard-coded string
Challenges & leaderboards	MOCK	Join/create buttons store nothing
Notifications	MOCK	Static list; no push capability
Achievements & records	MOCK	Badges hard-coded; PR logic stubbed
Share to social / community	UI ONLY	Beautiful flow, no delivery
Accounts & login	NONE	Profile is a local preferences file

What this means for launch

- ✗ Two users installing the app **see identical fake friends and posts** — trust is broken on day one
- ✗ A lost or replaced phone **wipes the user's entire history**
- ✗ Marketing cannot run challenges, referral or retention campaigns
- ✗ No analytics: we can't see usage, retention or device health

The good news

The hard part — a polished, feature-complete frontend — is **already done**. The app was architected with clean repository layers that are explicitly "backend-ready". We swap mock repositories for API calls; screens don't change.

THE PROPOSAL

A Python backend that switches every feature on

FastAPI — the modern Python framework used by Netflix and Microsoft — fronting PostgreSQL, Redis and push services. One platform powers every screen that exists today.

Every existing screen comes alive

No redesign needed — each screen below already exists. The backend simply replaces its fake data source.

Three phases — each one **independently demo-able**

We never disappear for months. Every phase ends with a working build in your hands.

The bottom line

Strolla Health has a launch-quality frontend wrapped around placeholder data. A focused 12-week Python backend turns every screen real, protects user data, and unlocks the community features the entire product is designed around. **Without it, the app cannot honestly go to market.**
